## 1. PRELUDE

Let  $k$  be a *perfect* field.

### 1.1. A classic Hartshorne problem.

1.1.1. *Hartshorne exercise III.7.something.* Let  $X$  be a smooth projective variety over  $k$  and let  $\iota : Z \hookrightarrow X$  be a *smooth* subvariety. Then the differential of  $\iota$  gives a morphism of sheaves

$$d\iota^\vee : \Omega_X^{\dim Z}|_Z \rightarrow \Omega_Z^{\dim Z} = \omega_Z$$

and an induced map on cohomology

$$H^{\dim Z}(X, \Omega_X^{\dim Z}) \xrightarrow{d\iota^\vee} H^{\dim Z}(Z, \omega_Z) \xrightarrow[\simeq]{\text{tr}} k,$$

an element of  $H^{\dim Z}(X, \Omega_X^{\dim Z})^\vee$ . Since we have a **perfect pairing**

$$\Omega_X^{\dim Z} \otimes \Omega_X^{\dim X - \dim Z} \xrightarrow{\wedge} \omega_X$$

$\Omega_X^{\dim Z} = \text{Hom}(\Omega_X^{\dim X - \dim Z}, \omega_X)$  and so **Serre duality** gives an isomorphism

$$H^{\dim Z}(X, \Omega_X^{\dim Z})^\vee \simeq H^{\dim X - \dim Z}(X, \Omega_X^{\dim X - \dim Z})$$

In this way we get a **cycle class**  $\text{cl}_X(Z) \in H^c(X, \Omega_X^c)$  with  $c = \text{codim}(Z, X)$ .

1.1.2. *Natural transformations out of Chow.* In fact, the above can be *upgraded* to show that Hodge cohomology  $H^d(X) := \bigoplus_{p+q=d} (X, \Omega_X^p)$  is *almost*<sup>1</sup> an example of a *Weil cohomology theory*. This means among other things that as a functor on, say, smooth projective varieties it's

- contravariant for arbitrary morphisms,
- covariant for proper morphisms,
- satisfies a Künneth formula of the form

$$H^d(X \times Y) = \bigoplus_{i+j=d} H^i(X) \otimes H^j(Y)$$

- comes with cycle classes  $\text{cl}_X(Z) \in H^c(X)$  for integral closed subschemes of codimension  $c$ , plus compatibilities for the above 3 bullet points. For example, for a dominant morphism  $f : X \rightarrow \mathbb{P}^1$ ,

$$\text{cl}_X([f^{-1}(0)]) = \text{cl}([f^{-1}(\infty)]) \in H(X)$$

See [dJ], [Mus]. As a consequence, the cycle class descends to a natural transformation  $\text{cl} : \text{CH} \rightarrow H$  compatible with pullbacks and pushforwards for proper morphisms.

**Example 1.1.** Set  $d = 1$ . Then we have a natural homomorphism

$$\text{Pic}(X) \simeq \text{CH}^1(X) \xrightarrow{\text{cl}} H^1(X, \Omega_X^1) \subset H^1(X)$$

which can be viewed as a 1st Chern class in Hodge cohomology. When  $k = \mathbb{C}$  we have a natural commutative diagram

$$\begin{array}{ccc} \text{Pic}(X) & \xrightarrow{\text{cl}} & H^1(X, \Omega_X^1) \\ \downarrow c_1 & \circlearrowleft & \downarrow \\ H^2(X, \mathbb{Z}) & \rightarrow & H^2(X, \mathbb{Z}) \otimes \mathbb{C} \simeq \bigoplus_{p+q=2} H^q(X, \Omega_X^p) \end{array}$$

The **Lefschetz theorem on (1,1)-classes** states that the image of  $\text{Pic}(X)$  in  $H^2(X, \mathbb{Z})$  is the preimage of  $H^1(X, \Omega_X^1)$ .

It's a remarkable fact that  $H^2(X, \mathbb{Z})$  classifies *topological* complex line bundles on  $X$  ("reason":  $\mathbb{C}\mathbb{P}^\infty$  is a  $K(\mathbb{Z}, 2)$ ). Hence Lefschetz's theorem tells us when a topological complex line bundle on  $X$  is (topologically isomorphic to) an *algebraic* one.

## 1.2. Idea: look at analogues for pairs/log schemes.

### 2. PAIRS

#### Definition 2.1.

- (1) A **simple normal crossing pair**  $(X, \Delta_X)$  is a smooth scheme over  $k$  together with a *reduced, effective* simple normal crossing divisor  $\Delta_X \subset X$ . The **interior**  $U_X \subset X$  of a simple normal crossing pair is  $U_X := X \setminus \Delta_X$ .
- (2) A **pulling morphism**  $f : (X, \Delta_X) \rightarrow (Y, \Delta_Y)$  of simple normal crossing pairs is a map of schemes  $f : X \rightarrow Y$  such that  $f(U_X) \subset U_Y$ .
- (3) A **pushing morphism**  $f : (X, \Delta_X) \rightarrow (Y, \Delta_Y)$  of simple normal crossing pairs is a *proper* map of schemes  $f : X \rightarrow Y$  such that  $f(U_X) \subset U_Y$  and  $f^*\Delta_Y - \Delta_X$  is effective..

#### 2.1. Log differentials.

<sup>1</sup>if  $\text{char } k > 0$  then the "coefficient field" will have positive characteristic.

2.1.1. *Classical case: differentials with log poles.* A log smooth pair  $(X, \Delta_X)$  comes with a sheaf of **differentials with log poles**  $\Omega_X^1(\log \Delta_X)$ . This naturally exists as the sheaf of differentials in the world of log geometry, but there's also a nice local description:

**Proposition 2.2.** *Let  $x \in X$  be a closed point and let  $z_1, \dots, z_n$  be local coordinates at  $x$  such that in a neighborhood of  $x$*

$$\Delta_X = V(z_1 \cdots z_r)$$

*Then near  $x$  the sheaf  $\Omega_X(\log \Delta_X)$  is freely generated by*

$$d \log z_1, \dots, d \log z_r, dz_{r+1}, \dots, dz_n$$

**Definition 2.3.** The **log Hodge cohomology of a simple normal crossing pair**  $(X, \Delta_X)$  is the graded abelian group  $H^\bullet(X, \Delta_X)$

$$H^d(X, \Delta_X) := \bigoplus_{p+q=d} H^q(X, \Omega_X(\log \Delta_X))$$

**Example 2.4.** When  $X$  is a smooth projective curve of genus  $g$ , there are only 2 sheaves of log differential forms to consider:

$$\Omega_X^0(\log \Delta_X) = \mathcal{O}_X \text{ and } \Omega_X^1(\log \Delta_X) = \omega_X(\Delta_X)$$

$h^0(\mathcal{O}_X) = 1$  and  $h^1(\mathcal{O}_X) = g$  per usual. Assume  $\Delta_X \neq 0$  – then  $\Delta_X$  is ample and since Kodaira vanishing always holds for curves,  $h^1(\omega_X(\Delta_X)) = 0$ . So,  $h^0(\omega_X(\Delta_X))$  can be calculated with Riemann-Roch:

$$h^0(\omega_X(\Delta_X)) = \chi(\omega_X(\Delta_X)) = g - 1 + \deg \Delta_X$$

2.1.2. *Log Hartshorne II.8.*

### 3. CHOW-OF-THE-COMPLEMENT

Chow for log schemes is a very active area of research. Here we use the most naïve possible version. For more interesting approaches, see e.g. [Bar], [BS17], [RS18]. There is also a growing body of work on algebraic K-theory of log schemes; see [Niz08], [Hag03].

#### 3.1. Complements and their Chow.

**Definition 3.1.** The **Chow groups of a simple normal crossing pair**  $(X, \Delta_X)$  are

$$\text{CH}(X, \Delta_X) := \text{CH}(U_X)$$

If  $f : (X, \Delta_X) \rightarrow (Y, \Delta_Y)$  is a pulling morphism, since  $f(U_X) \subset U_Y$  there's an induced morphism  $f^* : \text{CH}(Y, \Delta_Y) \rightarrow \text{CH}(X, \Delta_X)$ . If  $f$  is a pushing map, then the conditions  $f(U_X) \subset U_Y$  and  $f^* \Delta_Y - \Delta_X$  together require that  $U_X = f^{-1}(U_Y)$ , and hence  $f|_{U_X}$  is *proper*. So there's a pushforward  $f_* : \text{CH}(X, \Delta_X) \rightarrow \text{CH}(Y, \Delta_Y)$ .

3.1.1. *Example: curves.* Suppose  $X$  is a smooth projective curve. Then  $\Delta_X$  is just a bunch of points on  $X$  – say  $\Delta_X = \{p_0, \dots, p_N\}$ . For  $d = 0, 1$  we have right exact sequences

$$\text{CH}_d(\Delta_X) \xrightarrow{j_*} \text{CH}_d(X) \xrightarrow{i^*} \text{CH}_d(U_X) \rightarrow 0$$

when  $d = 1$  this shows  $\text{CH}_1(U_X) \simeq \text{CH}_1(X) \simeq \mathbb{Z}$ . When  $d = 0$ ,  $\text{CH}_0(\Delta_X) = \bigoplus_{i=0}^N \mathbb{Z}[p_i]$ , and we have the identifications  $\text{CH}_0(X) = \text{Cl}(X)$  and  $\text{CH}_0(U_X) = \text{Cl}(U_X)$ . Choose  $p_0$  as a basepoint for

$\text{Cl}(X)$  to get a splitting of the degree map  $\text{Cl}(X) \xrightarrow{\deg} \mathbb{Z}$ , hence a decomposition

$$\text{Cl}(X) \simeq \mathbb{Z}[p_0] \times \text{Cl}^0(X)$$

We now get a diagram

$$\begin{array}{ccccccc} \mathbb{Z}p_0 & \xrightarrow{\simeq} & \mathbb{Z}p_0 & \longrightarrow & 0 & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow & & \\ \bigoplus_{i=0}^N \mathbb{Z}p_i & \xrightarrow{j_*} & \mathbb{Z}p_0 \times \text{Cl}^0(X) & \longrightarrow & \text{CH}_0(U) & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow \simeq & & \\ \bigoplus_{i=1}^N \mathbb{Z}p_i & \longrightarrow & \text{Cl}^0(X) & \longrightarrow & \text{CH}_0(U) & \longrightarrow & 0 \end{array}$$

identifying  $\text{CH}_0(U)$  with the cokernel of the homomorphism

$$\bigoplus_{i=1}^N \mathbb{Z}p_i \rightarrow \text{Cl}^0(X) \text{ sending } [p_i] \mapsto [p_i] - [p_0]$$

#### 4. CONSTRUCTION OF A CYCLE CLASS

Even in the absolute case  $\Delta_X = 0$ , the construction of a cycle class  $\text{cl}_X(Z)$  for a subvariety  $Z \subset X$  is non-trivial (since  $Z$  may be arbitrarily singular). It was first carried out by El Zein in [EZ78], and the key ideas remain the same in the logarithmic setting.

**4.1. Setup.** Let  $(X, \Delta_X)$  be a simple normal crossing pair of dimension  $n$  and suppose  $Z \subset X$  is a closed subvariety (possibly singular) of co-dimension  $c$ , with  $Z \cap U_X \neq \emptyset$ . This means if  $\varphi^* : Z \rightarrow X$  is the inclusion then  $\varphi^*\Delta_X$  is a Cartier divisor on  $Z$ .

The construction that follows appears in [BS17]:

**4.2. Case 1 ( $Z$  is normal).** In this case the smooth locus of  $Z$  contains the generic points of all components of  $\varphi^*\Delta_X$ . Since  $k$  is perfect  $\text{supp } \Delta_X$  is generically smooth. Moreover the *non-simple normal crossing locus* of  $(Z, \Delta_Z)$  has codimension  $> 1$  in  $Z$  and hence  $> c + 1$  in  $X$ .

So, after removing a closed subset  $W \subset X$  with codimension  $> c + 1$  we may assume:  $Z$  is smooth and  $\varphi^*\Delta_X$  is a simple normal crossing divisor.

The local cohomology exact sequence for the sheaf  $\Omega_X^c(\log \Delta_X)$  at  $W$  reads

$$\begin{aligned} \cdots \rightarrow H_W^c(X, \Omega_X^c(\log \Delta_X)) &\rightarrow H^c(X, \Omega_X^c(\log \Delta_X)) \\ \cdots \rightarrow H^c(X \setminus W, \Omega_{X \setminus W}^c(\log \Delta_{X \setminus W})) &\rightarrow H_W^{c+1}(X, \Omega_X^c(\log \Delta_X)) \rightarrow \cdots \end{aligned}$$

We will make use of a lemma:

**Lemma 4.1.** *For a closed subset  $W \subset X$  of codimension  $r$ ,*

$$H_W^i(X, \Omega_X^c(\log \Delta_X)) = 0 \text{ for } i < r$$

$$\text{Hence } H^c(X, \Omega_X^c(\log \Delta_X)) = H^c(X \setminus W, \Omega_{X \setminus W}^c(\log \Delta_{X \setminus W})).$$

In the case where  $(Z, \Delta_Z)$  is smooth with simple normal crossings, apply Grothendieck Duality to the inclusion  $\varphi : Z \hookrightarrow X$  and the coherent sheaf  $\omega_Z(\Delta_Z)[\dim Z]$  to get a morphism

$$\begin{aligned} \varphi_* \mathcal{R}\mathcal{H}om_Z(\omega_Z(\Delta_Z)[\dim Z], \omega_Z[\dim Z]) &\simeq \mathcal{R}\mathcal{H}om_X(\varphi_* \omega_Z(\Delta_Z)[\dim Z], \omega_X[\dim X]) \\ &\xrightarrow{D(d\varphi^\vee)} \mathcal{R}\mathcal{H}om_X(\Omega_X^{\dim Z}(\log \Delta_X)[\dim Z], \omega_X[\dim X]) \end{aligned}$$

Using the perfect pairing

$$\Omega_X^p(\log \Delta_X) \otimes \Omega_X^{\dim X - p}(\log \Delta_X) \xrightarrow{\wedge} \omega_X(\Delta_X)$$

we have  $\mathcal{R}Hom_X(\Omega_X^p(\log \Delta_X), \omega_X) \simeq \Omega_X^{\dim X - p}(\log \Delta_X)(-\Delta_X)$  and similarly for  $Z$ , so that the morphism of [Theorem 4.2](#) can be rewritten as

$$\varphi_* \mathcal{O}_Z(-\Delta_Z) \xrightarrow{D(df^\vee)} \Omega_X^c(\log \Delta_X)(-\Delta_X)[c]$$

or using the projection formula,

$$\varphi_* \mathcal{O}_Z = \varphi_* \mathcal{O}_Z(\varphi^* \Delta_X - \Delta_Z) \xrightarrow{D(d\varphi^\vee)} \Omega_X^c(\log \Delta_X)[c]$$

Now take global sections and let  $\text{cl}_{(X, \Delta_X)}(Z)$  be the image of  $1_Z \in H^0(Z, \mathcal{O}_Z)$

**4.3. Case 2 (reduction to the normal case).** Since  $Z$  is a variety, its *normalization*  $\pi : \tilde{Z} \rightarrow Z$  is finite, and hence projective in the sense that there's a locally free sheaf  $\mathcal{F}$  on  $Z$  and a closed immersion  $\psi : \tilde{Z} \hookrightarrow \mathbb{P}(\mathcal{F})$  over  $Z$ . Since  $X$  is smooth we can find a  $\mathcal{F}$  of the form  $\mathcal{F} = \mathcal{E}|_Z$  where  $\mathcal{E}$  is locally free on  $X$ , and in this way we get a commutative diagram

$$\begin{array}{ccccc} \tilde{Z} & \xrightarrow{\psi} & \mathbb{P}(\mathcal{E}|_Z) & \xrightarrow{\varphi'} & \mathbb{P}(\mathcal{E}) \\ & \searrow \pi & \downarrow \rho' & \square & \downarrow \rho \\ & & Z & \xrightarrow{\varphi} & X \end{array}$$

Here  $\tilde{Z} \subset \mathbb{P}(\mathcal{E})$  is normal and  $\mathbb{P}(\mathcal{E})$  is smooth. Setting  $\Delta_{\mathbb{P}(\mathcal{E})} = \rho^* \Delta_X$ , we obtain a class  $\text{cl}_{\mathbb{P}(\mathcal{E})}(\tilde{Z}) \in H^\bullet(\mathbb{P}(\mathcal{E}), \Omega_{\mathbb{P}(\mathcal{E})}^\bullet(\log \Delta_{\mathbb{P}(\mathcal{E})}))$ .

The trick now is to set  $\text{cl}_X(Z) = \rho_* \text{cl}_{\mathbb{P}(\mathcal{E})}(\tilde{Z})$ .
