1. Introduction

In [CR11] Chatzistamatiou and Rülling prove the following theorem:

Theorem 1.1 ([CR11, Thm. 3.2.8]). Let k be a perfect field and let S be a separated scheme of finite type over k. Suppose X and Y are two separated finite type S-schemes which are

- (i) smooth over k and
- (ii) *properly birational* over S in the sense that there is a commutative diagram

with r and s proper birational morphisms.

Set $n = \dim X = \dim Y = \dim Z$. Then there are natural morphisms of sheaves

$$\operatorname{cl}_{Z}^{j}: R^{j} f_{*} \Omega_{X}^{i} \to R^{j} g_{*} \Omega_{Y}^{i} \text{ for all } i,$$
 (1.3)

which are isomorphisms if i = 0, n.

Date: October 5, 2020.

The author was partially supported by the University of Washington Department of Mathematics Graduate Research Fellowship, and by the NSF grant DMS-1440140, administered by the Mathematical Sciences Research Institute, while in residence at MSRI during the program Birational Geometry and Moduli Spaces.

In the special case char k=0 this is a consequence of Hironaka's resolution of singularities [Hir64]. Analysis of the proof shows that the morphisms of 1.3 are obtained from morphisms of *complexes*

$$\operatorname{cl}_Z: Rf_*\Omega_X^i \to Rg_*\Omega_Y^i$$
 for all i ,

(for the cases i = 0, n this is observed in [CR12; Kov19]).

One of the primary applications of Theorem 1.1 was to extend foundational results on rational singularities from characteristic zero to arbitrary characteristic.

Definition 1.4 ([Kol13, Def. 2.76]). Let *S* be a reduced, separated scheme of finite type over a field k. A **rational resolution** $f: X \to S$ is a proper birational morphism such that

- (i) X is smooth over k,
- (ii) $\mathcal{O}_S = Rf_*\mathcal{O}_X$ and
- (iii) $R^i f_* \omega_X = 0$ for i > 0.

The scheme *S* is said to have **rational singularities** if and only if it has a rational resolution.

Corollary 1.5 ([CR11, Cor. 3.2.10]). *If* S *has a rational resolution, then every resolution of* S *is rational. In particular if* S *is smooth then it has rational singularities.*

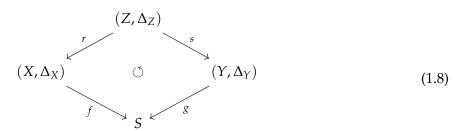

This article concerns analogues of Theorem 1.1 for pairs.

Convention 1.6. In what follows a **pair** (X, Δ_X) will mean a reduced, equidimensional separated scheme X of finite type over k together with a reduced, effective divisor Δ_X on X. A pair (X, Δ_X) will be called a **simple normal crossing (snc) pair** if and only if X is smooth and X is a simple normal crossing divisor on X.

As observed in [Kol13, §2.5], to generalize Corollary 1.5 to pairs we must restrict attention to a special class of *thrifty resolutions* (Definition 3.5).

Theorem 1.7. Let k be a perfect field and let S be a separated scheme of finite type over k. Let (X, Δ_X) and (Y, Δ_Y) be simple normal crossing pairs over S.

Suppose (X, Δ_X) , (Y, Δ_Y) are properly birational over S in the sense that there is a commutative diagram

where r, s are proper and birational morphisms, and $\Delta_Z = r_*^{-1} \Delta_X = s_*^{-1} \Delta_Y$. Set $n = \dim X = \dim Y = \dim Z$. If r, s are thrifty then there are quasi-isomorphisms

$$Rf_*\mathcal{O}_X(-\Delta_X) \simeq Rg_*\mathcal{O}_Y(-\Delta_Y)$$
 and $Rf_*\omega_X(\Delta_X) \simeq Rg_*\omega_Y(\Delta_Y)$. (1.9)

Definition 1.10 ([Kol13, Def. 2.78]). Let (S, Δ_S) be a pair as in Convention 1.6, and suppose S is normal. A **rational resolution of** (S, Δ_S) is a proper birational morphism $f: X \to S$ such that if $\Delta_X = f_*^{-1} \Delta_S$ then

- (*i*) The pair (X, Δ_X) is snc,
- (ii) The natural map $\mathcal{O}_S(-\Delta_S) \to Rf_*\mathcal{O}_X(-\Delta_X)$ is a quasi-isomorphism, and
- (iii) $R^i f_* \omega_X(\Delta_X) = 0$ for i > 0.

Remark 1.11 (description of the natural map in (ii)). Since Δ_X is the strict transform of Δ_S , so in particular $\Delta_X \subset f^{-1}(\Delta_S)$, there is a containment of ideal sheaves $\mathcal{I}_{f^{-1}(\Delta_S)} \subset \mathcal{I}_{\Delta_X} = \mathcal{O}_X(-\Delta_X)$ providing a morphism

$$f^*\mathcal{O}_S(-\Delta_S) = f^*\mathcal{I}_{\Delta_S} \to \mathcal{I}_{f^{-1}(\Delta_S)} \subset \mathcal{I}_{\Delta_X} = \mathcal{O}_X(-\Delta_X).$$

Taking the adjoint gives a morphism $\mathcal{O}_S(-\Delta_S) \to f_*\mathcal{O}_X(-\Delta_X)$, and composing with the natural map $f_*\mathcal{O}_X(-\Delta_X) \to Rf_*\mathcal{O}_X(-\Delta_X)$ gives (ii).

As a straightforward corollary of Theorem 1.7, one obtains:

Corollary 1.12. Let (S, Δ_S) be a pair, with Δ_S reduced and effective. If (S, Δ_S) has a thrifty rational resolution $f:(X,\Delta_X)\to (S,\Delta_S)$, then every thrifty resolution $g:(Y,\Delta_Y)\to (S,\Delta_S)$ is rational. In particular, if (S,Δ_S) is snc then it is a rational pair.

1.1. **Acknowledgements.** The author would like to thank Jarod Alper, Daniel Bragg, Chi-yu Cheng, Kristin DeVleming, Gabriel Dorfsman-Hopkins, Max Lieblich, and Tuomas Tajakka for helpful conversations, and his advisor Sándor Kovács for years of guidance and encouragement, as well as proposing the problem of extending Theorem 1.1 to pairs. Special thanks to Karl Schwede for suggesting the strategy, pursued in Sections 4 and 5, of using derived category techniques to leverage the results of [CR11; Kov19].

2. Dual complexes

Definition 2.1 (cf. [dFKX14]). Let $Z = \bigcup_{i \in I} Z_i$ be a scheme with irreducible components Z_i . Say Z is an **expected-dimensional crossing scheme** if and only if

- (i) Z is pure dimensional and the components Z_i are normal, and
- (ii) For any $J \subset I$, set $Z_J := \bigcap_{j \in J} Z_j$. If $\hat{Z}_J \neq \emptyset$ every connected component of Z_J is irreducible and of codimension |J| 1 in Z.

A **stratum** of an expected-dimensional crossing scheme Z is an irreducible (or equivalently connected) component of $Z_I = \bigcap_{i \in I} Z_i$ for some $J \subset I$.

The main case of Definition 2.1 considered here will be the case $\Delta = \Delta_X$ where (X, Δ_X) is a simple normal crossing pair, in which case all strata of Δ_X are smooth.

Let (X, Δ_X) be a simple normal crossing pair, and write $\Delta_X = \bigcup_{i \in I} D_i$ with D_i the irreducible components of Δ_X . For $J \subset I$, let $D_J = \bigcap_{j \in J} D_j$, and write $D_J = \bigcup_k D_J^k$ where the D_J^k are irreducible. Observe that $(\Delta_X - \sum_{i \in J} D_i)|_{D_J^k}$ is a (possibly empty) simple normal crossing divisor on each stratum D_I^k .

Definition 2.2 (strata as pairs).

$$\Delta_{D_J} := (\Delta_X - \sum_{i \in J} D_i)|_{D_J}$$
 and $\Delta_{D_J^k} := (\Delta_X - \sum_{i \in J} D_i)|_{D_J^k}$

Definition 2.3. For an expected-dimensional crossing scheme $Z = \bigcup_{i \in I} Z_i$, the **dual complex** $\mathcal{D}(Z)$ is a Δ -complex [Hat02, §2.1] that can be described as follows: assume the index set I has been totally ordered. For each $d \in \mathbb{N}$, the d-simplices of $\mathcal{D}(Z)$ correspond to the irreducible components $Z_J^k \subset Z_J = \cap_{j \in J} Z_j$ where $J \subset I$ ranges over all subsets of size |J| = d + 1. Let σ_J^k be the d-simplex associated to Z_I^k .

If $j \in J$ write $\hat{J}(j) := J \setminus \{j\}$ – we have inclusions $Z_J \subset Z_{\hat{J}(j)}$, and the connected components of $Z_{\hat{J}(j)}$ are irreducible, for each component Z_J^k there is a *unique* component $Z_{\hat{J}(j)}^l \subset Z_{\hat{J}(j)}$ such that $Z_J^k \subset Z_{\hat{J}(j)}^l$. The face maps of $\mathcal{D}(Z)$ are obtained by setting

$$\partial_j \sigma_J^k = \sigma_{\hat{J}(j)}^l$$

Remark 2.4. In particular, $\mathcal{D}(Z)$ has

- 0-simplices σ_i corresponding to the irreducible components $Z_i \subset Z$,
- 1-simplices σ_{ij}^k corresponding to the components $Z_{ij}^k \subset Z_{ij} = Z_i \cap Z_j$ where i < j, with face maps ∂_0 , ∂_1 corresponding to the inclusions $Z_{ij}^k \subset Z_i$, $Z_{ij}^k \subset Z_j$ respectively,

and so on.

Remark 2.5. From the description above one can see that $\mathcal{D}(Z)$ is a **regular** Δ-complex, meaning that if $\sigma \subseteq \mathcal{D}(Z)$ is a *d*-simplex, the corresponding map $\sigma \colon \Delta^d \to \mathcal{D}(Z)$ is injective. Indeed, if

$$\partial_j \sigma_I^k = \partial_{j'} \sigma_I^k$$

for $j \neq j'$, then $Z_{\hat{J}(j)} \cap Z_{\hat{J}(j')} = Z_J$ would contain a component of codimension d-1, violating (ii) of Definition 2.3.

Dual complexes have been extensively studied; to paraphrase Arapura, Bakhtary, and Włodarczyk, $\mathcal{D}(Z)$ governs the *combinatorial part* of the topology of Z [ABW13]. One underlying reason for this is

Lemma 2.6 (Special case of [Fri83, Prop. 1.5]¹). *If* Δ *is a simple normal crossing scheme and* $n = \dim \mathcal{D}(\Delta)$, then there is a quasi-isomorphism

$$\mathcal{O}_{\Delta} \simeq \left[\prod_{\sigma \in \mathcal{D}(\Delta)^0} \mathcal{O}_{D(\sigma)} \xrightarrow{d^1} \prod_{\sigma \in \mathcal{D}(\Delta)^1} \mathcal{O}_{D(\sigma)} \xrightarrow{d^2} \cdots \rightarrow \prod_{\sigma \in \mathcal{D}(\Delta)^n} \mathcal{O}_{D(\sigma)}\right] =: \check{C}(\Delta, \mathcal{O}) \ in \ D^+(\Delta_X)$$

where the differential d^i : $\prod_{\sigma \in \mathcal{D}(\Delta)^{i-1}} \mathcal{O}_{D(\sigma)} \to \prod_{\sigma \in \mathcal{D}(\Delta)^i} \mathcal{O}_{D(\sigma)}$ has σ th coordinate

$$\prod_{\sigma \in \mathcal{D}(\Delta)^{i-1}} \mathcal{O}_{D(\sigma)} \to \prod_{j=0}^i \mathcal{O}_{D(\partial^j \sigma)} \xrightarrow{\sum_{j=0}^i (-1)^j \mathrm{res}_j} \mathcal{O}_{D(\sigma)}$$

and where $\operatorname{res}_j: \mathcal{O}_{D(\partial^j \sigma)} \to \mathcal{O}_{D(\sigma)}$ is the natural map restricting functions.

Corollary 2.7. If (X, Δ_X) is a simple normal crossing pair let $n = \dim \mathcal{D}(\Delta_X)$, then there is a quasi-isomorphism

$$\mathcal{O}_X(-\Delta_X)\simeq [\mathcal{O}_X \xrightarrow{d^0} \prod_{\sigma\in\mathcal{D}(\Delta)^0} \mathcal{O}_{D(\sigma)} \xrightarrow{d^1} \prod_{\sigma\in\mathcal{D}(\Delta)^1} \mathcal{O}_{D(\sigma)} \xrightarrow{d^2} \cdots o \prod_{\sigma\in\mathcal{D}(\Delta)^n} \mathcal{O}_{D(\sigma)}]=:\check{C}(X,\Delta_X,\mathcal{O})$$

in $D^+(X)$.

Proof. We must show that the sequence

$$\mathcal{O}_X(-\Delta_X) \to \mathcal{O}_X \xrightarrow{d^0} \prod_{\sigma \in \mathcal{D}(\Delta)^0} \mathcal{O}_{D(\sigma)} \xrightarrow{d^1} \prod_{\sigma \in \mathcal{D}(\Delta)^1} \mathcal{O}_{D(\sigma)} \xrightarrow{d^2} \cdots \to \prod_{\sigma \in \mathcal{D}(\Delta)^n} \mathcal{O}_{D(\sigma)}$$

is exact – Lemma 2.6 already implies $\ker d^i = \operatorname{im} d^{i-1}$ for i > 1 and $\ker d^1 = \mathcal{O}_\Delta$. Exactness of the sequence $0 \to \mathcal{O}_X(-\Delta_X) \to \mathcal{O}_X \to \mathcal{O}_{\Delta_X} \to 0$ tells us that $\mathcal{O}_X \to \mathcal{O}_{\Delta_X}$ is surjective with kernel $\mathcal{O}_X(-\Delta_X)$. Hence defining d^0 to be the composition

$$\mathcal{O}_X \xrightarrow{d^0} \mathcal{O}_{\Delta_X} \longrightarrow \prod_{\sigma \in \mathcal{D}(\Delta)^0} \mathcal{O}_{D(\sigma)}$$
 (2.8)

ensures that $\ker d^1 = \operatorname{im} d^0$ and that $\ker d^0 = \mathcal{O}_X(-\Delta_X)$, as desired.

¹The cited proposition is stated over C, but the proof works in arbitrary characteristic.

2.1. **Morphisms of Dual Complexes.** One can extract from the literature on dual complexes the following slogan:

Morphisms of pairs induce morphisms of dual complexes. Moreover, there is a "dictionary" relating properties of a morphism of pairs with corresponding properties of the induced morphism of dual complexes.

To precisify the slogan, we include a foundational result providing a weak sort of functoriality.

Lemma 2.9 (cf. [Wlo16, Def. 2.0.6]). Let $Z = \bigcup_{i \in I} Z_i$ and $W = \bigcup_{j \in J} W_j$ be expected -dimensional crossing schemes and let $f: Z \dashrightarrow W$ be a rational morphism defined at the generic point of each stratum of Z. Then up to homotopy equivalence there is a unique induced morphism of Δ -complexes

$$\mathcal{D}(f):\mathcal{D}(Z)\to\mathcal{D}(W)$$

such that if $\sigma \subset \mathcal{D}(Z)$ is a simplex and η_{σ} is the generic piont of the corresponding stratum of Z, and if $\tau \subset \mathcal{D}(W)$ is the simplex corresponding to the unique minimal stratum $D(\tau) \subset W$ containing $f(\eta_{\sigma})$, then $\mathcal{D}(f)(\sigma) \subset \tau$.

Proof in the case f is defined everywhere. Since $f(D(\sigma))$ is irreducible it is contained in some stratum of W (in particular, $f(D(\sigma)) \subset W_i$ for some i). Let

$$W_J := \cap \{W_j \subset W \mid f(D(\sigma)) \subset W_j\}$$

By (ii) of Definition 2.1, the connected components of W_J are irreducible, and hence $f(D(\sigma))$ is contained in exactly one of them – let $\tau \subset \mathcal{D}(W)$ be the corresponding simplex. If dim $\sigma = 0$ let $\mathcal{D}(f)(\sigma)$ be an interior point of τ .

One can now show by induction on $\dim \sigma$ that $\mathcal{D}(f)$ extends over all of $\mathcal{D}(Z)$ – so, assume $\dim \sigma > 1$. For each face $\sigma' \subset \sigma$ with corresponding stratum $D(\sigma') \subset Z$, let $D(\tau') \subset W$ be the smallest stratum containing $f(D(\sigma'))$. Now

$$f(D(\sigma)) \subset f(D(\sigma'))$$
 forces $D(\tau) \subset D(\tau')$

and this gives an inclusion $\iota_{\tau'}: \tau' \to \tau$. By induction a map $\mathcal{D}(f)|_{\sigma'}: \sigma' \to \tau'$ has already been defined, so composing with ι one obtains

$$\sigma' \xrightarrow{\mathcal{D}(f)|_{\sigma'}} \tau' \xrightarrow{\iota} \tau$$
 for each face $\sigma' \subset \sigma$

which together give a map $\partial \sigma \to \tau$, and as τ is contractible this map must extend over σ . Uniqueness up to homotopy equivalence follows from Lemma 2.10.

Lemma 2.10. If $f,g: X \to Y$ are 2 maps of regular Δ -complexes such that for each simplex $\sigma \subseteq X$ there is a unique minimal simplex $\tau_{\sigma} \subseteq Y$ such that $f(\sigma), g(\sigma) \subseteq \tau_{\sigma}$ then there is a homotopy $h: X \times I \to Y$ from f to g such that $h(\sigma \times I) \subseteq \tau_{\sigma}$ for each simplex $\sigma \subset X$.

Proof. We proceed by induction over the skeleta $X^d \subseteq X$. For the case d=0 let $v \in X^0$ be a vertex. By hypothesis there's a unique minimal simplex $\tau_v \subseteq Y$ so that $f(v), g(v) \in \tau_v \subseteq Y$, so we may choose a path $\gamma_v \colon I \to \tau_v \subseteq Y$ with $\gamma_v(0) = f(v), \gamma_v(1) = g(v)$. Then the map

$$h^0 \colon X^0 \times I \to Y$$
 defined by $h^0(v,t) = \gamma_v(t)$

is a homotopy between $f|_{X^0}$ and $g|_{X^0}$ with $h^0(\{v\} \times I) \subseteq \tau_v$ for all v.

Suppose by inductive hypothesis that d>0 and we have constructed a homotopy $h^{d-1}\colon X^{d-1}\times I\to Y$ from $f|_{X^{d-1}}$ to $g|_{X^{d-1}}$ with $h^{d-1}(\sigma\times I)\subseteq \tau_\sigma$ for all simplices $\sigma\subseteq X^{d-1}$. Let $\sigma\subset X$ be a d-simplex, and observe that if $\sigma'\subset \sigma$ is a face then $f(\sigma')\subseteq f(\sigma)\subseteq \tau_\sigma$, and similarly $g(\sigma')\subseteq \tau_\sigma$. By hypothesis this implies $\tau_{\sigma'}\subseteq \tau_\sigma$, so that the homotopy $h^{d-1}|_{\sigma'}\colon \sigma'\times I\to Y$ factors through τ_σ . We

conclude that the map $\gamma \tilde{|}_{\sigma} : \sigma \times 0, 1 \cup \partial \sigma \rightarrow Y$ defined by

$$(x,t) \mapsto \begin{cases} f(x) & \text{if } t = 0, \\ g(x) & \text{if } t = 1, and \\ h(x,t), & \text{otherwise} \end{cases}$$

factors through τ_{σ} ; since Y is regular τ_{σ} is contractible, and so $\tilde{\gamma}|_{\sigma}$ extends to a morphism $\gamma_{\sigma} : \sigma \times I \to Y$. As σ varies over the d-simplices of X, the γ_{σ} provide an extension of h^{d-1} to a homotopy

$$h^d: X^d \times I \to Y$$
 from $f|_{X^d}$ to $g|_{X^d}$.

3. THRIFTY MORPHISMS OF PAIRS

Let (S, Δ_S) be a pair (as in Convention 1.6).

Definition 3.1. The **snc locus of** (S, Δ_S) is the largest open $U \subset S$ so that $(U, \Delta_S|_U)$ is a simple normal crossing pair – it will be denoted $\operatorname{snc}(S, \Delta_S)$. We also set

$$non-snc(S, \Delta_S) := S \setminus snc(S, \Delta_S)$$
(3.2)

Remark 3.3. When *S* is normal, non-snc(S, Δ_S) has codimension ≥ 2 in *S*.

In their work on dual complexes of Calabi-Yau pairs, introduced a natural generalization of thrifty resolutions to a class of *thrifty morphisms* where the domain is no longer required to be smooth.

Definition 3.4 ([KX16, Def. 9]). A crepant proper birational morphism of log canonical pairs $f: (X, \Delta_X) \dashrightarrow (S, \Delta_S)$ is **Kollár-Xu-thrifty** (KX-thrifty for short) if and only if there are closed subsets $Z_X \subset X$, $Z_S \subset S$ of codimension ≥ 1 so that

- Z_X contains no log canonical centers of (X, Δ_X) , and similarly for Z_S , and
- f restricts to an isomorphism $X \setminus Z_X \stackrel{f}{\underset{\sim}{\simeq}} S \setminus Z_S$.

Since rational pairs are not log canonical in general, for example since they are not necessarily Q-Gorenstein², we adopt a slightly different definition of thrifty morphisms (see Lemma 3.8 for a comparison).

Let (S, Δ_S) be a pair and let $f: X \to S$ be a proper birational morphism. Set $\Delta_X := f_*^{-1} \Delta_S$ (the strict transform).

Definition 3.5. The morphism *f* is **thrifty** if and only if

- (i) f is an isomorphism *over* the generic point of every stratum of $\operatorname{snc}(S, \Delta_S)$ and
- (ii) f is an isomorphism at the generic point of every stratum of $\operatorname{snc}(X, \Delta_X)$.

If in addition *X* is smooth and $f^{-1}(\Delta_S) \cup E$ is a simple normal crossing divisor (with *E* the exceptional locus) then *f* is called a **thrifty resolution**.

Remark 3.6. Equivalently, if $Ex(f) \subset X$ is the exceptional locus of f, then

- (i) f(Ex(f)) contains no stratum of $Snc(S, \Delta_S)$ and
- (ii) Ex(f) contains no stratum of snc(X, Δ_X).

Remark 3.7. Hence when X is smooth and $f^{-1}(\Delta_S) \cup E$ is a simple normal crossing divisor Definition 3.5 reduces to [Kol13, Def. 2.79].

Lemma 3.8. Let $f: (X, \Delta_X) \to (S, \Delta_S)$ be a crepant proper birational morphism between dlt pairs. Then f is KX-thrifty (Definition 3.4) if and only if it is thrifty (Definition 3.5).

The cone over $\mathbb{P}^1 \times \mathbb{P}^1 \subseteq \mathbb{P}^{mn+m+n}$ embedded using the complete linear system $|\mathcal{O}_{\mathbb{P}^1 \times \mathbb{P}^1}(m,n)|$ is rational for all m, n > 0, Q-Gorenstein if and only if m = n.

Proof. The map f is crepant, so $K_X + \Delta_X \sim_{\mathbb{Q}} f^*(K_S + \Delta_S)$ – equivalently,

$$\Delta_X \sim_{\mathbb{Q}} f_*^{-1}(\Delta_S) - \sum_i a_i E_i$$

where $a_i := a(E_i, S, \Delta_X)$ and the sum runs over all f-exceptional divisors $E_i \subset X$. Writing $\Delta_S = \sum_i c_i D_i$, we see that $\Delta_S^{=1} = \sum_{c_i=1} D_i$ and that $\Delta_X^{=1} = \sum_{c_i=1} f_*^{-1} D_i + \sum_{a_i=-1} E_i$. Both pairs are dlt, so the log canonical centers of (X, Δ_X) are the strata of the expected-dimensional crossing scheme $\Delta_X^{=1}$, and their generic points lie in $\operatorname{snc}(X, \Delta_X)$ – similarly for (S, Δ_S) [Fuj07]. Moreover, if $a_i = -1$ then $f(E_i) \subset S$ is a log canonical center, so it must be a stratum of $\Delta_S^{=1}$.

Suppose f is KX-thrifty and let $Z_X \subset X$, $Z_S \subset S$ be closed sets as guaranteed in Definition 3.4. Then f is an isomorphism over $S \setminus Z_S$ and Z_S contains no stratum of $\Delta_S^{=1}$, giving condition (i) of Definition 3.5. Also, we must have $a_i > -1$ for all i, and so $\Delta_X^{=1} = \sum_{c_i=1} f_*^{-1} D_i = f_*^{-1} \Delta_S^{=1}$. Since Z_X contains no stratum of $\Delta_X^{=1}$, we obtain (ii) of Definition 3.5.

In the next lemma we use a definition of a birational map general enough to encompass reducible schemes [Sta19, Tags 0A20, 0BX9]: a rational map $f: X \longrightarrow Y$ between schemes with finitely many irreducible components is *birational* if and only if it is an isomorphism in the category with

- objects the schemes with finitely many irreducible components, and with
- morphisms the dominant rational maps between them.

When Y is locally of finite presentation over a field (as it will be in all cases considered here), the map f is birational if and only if it induces a bijection between the generic points of irreducible components of X and Y, and for each generic point of an irreducible component $\eta \in X$ the induced morphism $\mathcal{O}_{Y,f(\eta)} \to \mathcal{O}_{X,\eta}$ is an isomorphism.

Lemma 3.9. Let $Z = \bigcup_{i=1}^{N} Z$ and $W = \bigcup_{j=1}^{N} W_j$ be expected-dimensional crossing schemes and let $f: Z \dashrightarrow W$ be a birational map defined at the generic point of each stratum of Z.

- (i) If f is an isomorphism at the generic point of every stratum $D(\sigma) \subset Z$, then $\mathcal{D}(f)$ can be realized as a subcomplex inclusion.
- (ii) If f is an isomorphism over the generic point of every stratum $D(\tau) \subset W$ then it is an isomorphism at the generic point of every stratum of Z, and D(f) can be realized as an isomorphism of Δ -complexes.

Proof. In the case of (i), as f is birational it induces a bijection between the generic points of Z and W and hence a bijection on 0-skeleta

$$\mathcal{D}(f)_0: \mathcal{D}(Z)_0 \xrightarrow{\simeq} \mathcal{D}(W)_0$$

Without loss of generality we may assume f restricts to a birational maps $f_i: Z_i \dashrightarrow W_i$ for i = 1, ..., N. Let $n = \dim Z = \dim W$.

Let $\sigma \subset \mathcal{D}(Z)$ be a simplex with corresponding stratum $D(\sigma) \subset Z$ – without loss of generality we may assume $D(\sigma) \subset Z_1$, and that $D(\sigma) \subseteq \cap_{j=1}^r Z_j$. Letting $\eta_{\sigma} \in D(\sigma)$ be the generic point, we see that $f(\eta_{\sigma}) \subset \cap_{j=1}^r W_j$. Because f is an isomorphism at η_{σ} , it must be that $f(\eta_{\sigma})$ is a generic point of a component $D(\tau) \subseteq \cap_{j=1}^r W_j$ corresponding to a simplex $\tau \subseteq \mathcal{D}(W)$. Let $\eta_{\tau} \in D(\tau)$ be the generic point; we have $\eta_{\tau} = f(\eta_{\sigma})$.

At this point the only concern is that there could be another r-1-simplex σ' such that $\mathcal{D}(f)(\sigma')=\tau$; any such σ' would correspond to another stratum $D(\sigma')\subseteq \cap_{j=1}^r Z_j$, hence another point $\eta_{\sigma'}\in Z_1$ of dimension r-1 with $f(\eta'_{\sigma})=f(\eta_{\tau})$. One can show this is impossible, using the normality of W_1 and Zariski's main theorem as follows.

The map f is an isomorphism at the generic point $n_{\sigma} \in D(\sigma)$, so its restriction $f|_{Z_1} \colon Z_1 \to W_1$ is also an isomorphism at n_{σ} . The scheme W_1 is normal and $f|_{Z_1}$ is birational by hypothesis, so by Zariski's main theorem [Sta19, Tag 05K0] $f|_{Z_1}$ is in fact an isomorphism *over* η_{τ} .

For (ii), observe that $f^{-1}: W \dashrightarrow Z$ satisfies the hypotheses of (i) and hence both $\mathcal{D}(f): \mathcal{D}(Z) \to \mathcal{D}(W)$ and $\mathcal{D}(f^{-1}): \mathcal{D}(W) \to \mathcal{D}(W)$ may be realized as subcomplex inclusions; from the proof of

(i), this can be done in such a way that $\mathcal{D}(f) \circ \mathcal{D}(f^{-1}) = \mathrm{id}_{\mathcal{D}(W)}$. In particular this implies $\mathcal{D}(f)$ is a surjective subcomplex inclusion, hence an isomorphism.

Corollary 3.10. Let (S, Δ_S) be a pair and let $f: X \to S$ be a proper birational morphism and set $\Delta_X := f_*^{-1} \Delta_S$. Then f induces morphisms of Δ -complexes

$$\mathcal{D}(\operatorname{snc}\Delta_X) \xrightarrow{\mathcal{D}(f|_{\Delta})} \mathcal{D}(\operatorname{snc}\Delta_S) \text{ and } \mathcal{D}(\operatorname{snc}(X,\Delta_X)) \xrightarrow{\mathcal{D}(f)} \mathcal{D}(\operatorname{snc}(S,\Delta_S))$$

which are isomorphisms if f is thrifty.

Proof. The induced morphisms come from Lemma 2.9; to see that they are isomorphisms when f is thrifty we may apply Definition 3.5 and Lemma 3.9.

3.1. **Thrifty proper birational equivalences.** If *S* is a separated scheme of finite type over *k* and $f: X \to S$, $g: Y \to S$ are separated schemes of finite type over *S*, a **proper birational equivalence of** *X*, *Y* **over** *S* is a commutative diagram

where r, s are proper birational morphisms.

Definition 3.12. Suppose (X, Δ_X) , (Y, Δ_Y) are pairs over S, with X and Y normal and Δ_X, Δ_Y reduced and effective. A **thrifty proper birational equivalence of** (X, Δ_X) **and** (Y, Δ_Y) **over** S is a proper birational equivalence as in diagram 3.11, where r and s are thrifty.

Remark 3.13. By Corollary 3.10, a thrifty proper birational equivalence $X \xleftarrow{r} Z \xrightarrow{s} Y$ between (X, Δ_X) and (Y, Δ_Y) induces an isomorphism $\mathcal{D}(\Delta_X) \simeq \mathcal{D}(\Delta_Y)$.

Proposition 3.14. *Let* (S, Δ_S) *be a pair with* Δ_S *reduced and effective, and let* $f: X \to S$, $g: Y \to S$ *be* 2 *thrifty resolutions of* (S, Δ_S) . *Then there is a thrifty proper birational equivalence of* X *and* Y *over* S.

Proof. Let $U \subset S$ be an open set such that both f and g are isomorphisms over U; then we have an isomorphism

$$g^{-1} \circ f : f^{-1}(U) \to g^{-1}(U)$$

Set

$$Z := \overline{\Gamma_{g^{-1} \circ f}} \subset X \times_S Y$$

and let $p: Z \to X$, $s: Z \to Y$ be the projections. The claim is that $X \xleftarrow{r} Z \xrightarrow{s} Y$ is a thrifty proper birational equivalence over S. It is birational by design, and proper since X, Y and hence $X \times_Y Z$ are proper over S and Z is closed in $X \times_S Y$. It remains to show that r, s are thrifty.

Lemma 3.15. *Let* Ex(r), $Ex(s) \subset Z$ *be the exceptional loci of r, s respectively; let* $Ex(f) \subset X$, $Ex(g) \subset Y$ *be the exceptional loci of f and g. Then*

$$r(\operatorname{Ex}(r)) \subset f^{-1}(g(\operatorname{Ex}(g)))$$
 and $s(\operatorname{Ex}(s)) \subset g^{-1}(f(\operatorname{Ex}(f)))$

Proof of Lemma 3.15. Let $U \subset S$ and $V \subset Y$ be a maximal pair of open sets such that $g|_V : V \xrightarrow{\simeq} U$ is an isomorphism; note that since g is an honest morphism $\operatorname{Ex}(g) = Y \setminus V$ and $g(\operatorname{Ex}(g)) = S \setminus U$. Then $W := f^{-1}(U) \subset X$ is an open set such that $g^{-1} \circ f : X \dashrightarrow Y$ is defined on W. This implies

the projection $\Gamma_{g^{-1} \circ f} \xrightarrow{r} X$ is an isomorphism over W, but what we need to know is that the same is true for $Z = \bar{\Gamma}_{g^{-1} \circ f} \xrightarrow{r} X$. For this, note that

$$\overline{\Gamma}_{g^{-1}\circ f}\cap r^{-1}(W)=\overline{\Gamma_{g^{-1}\circ f}\cap r^{-1}(W)}=\overline{\Gamma_{g^{-1}\circ f|_{W}}}\subset W\times_{S}Y$$

Since W and Y are both separated over S, the graph $\Gamma_{g^{-1}\circ f|_W}$ is already closed, so we conclude $\bar{\Gamma}_{g^{-1}\circ f}\cap r^{-1}(W)=\Gamma_{g^{-1}\circ f|_W}$.

Now suppose $W \subset X$ is a stratum of (X, Δ_X) – we must show r is an isomorphism over the generic point $\eta \in W$. First, f is an isomorphism at η by hypothesis, and so by the proof of Lemma 3.9, $f(\eta)$ is the generic point of a stratum of $\mathrm{snc}(S, \Delta_S)$. Then g is an isomorphism over $f(\eta)$ by hypothesis, so in particular $f(\eta) \notin g(\mathrm{Ex}(g))$. By Lemma 3.15 we conclude that $\eta \notin r(\mathrm{Ex}(r))$, as desired.

Finally we show that s is an isomorphism at the generic point of every stratum of $\Delta_Z := r_*^{-1} f_*^{-1} \Delta_S$, using a more general lemma:

Lemma 3.16. Let $r: (Z, \Delta_Z) \to (X, \Delta_X)$ be a proper birational morphism. If (X, Δ_X) is a simple normal crossing pair, then r is thrifty if and only if it satisfies condition (i) of Definition 3.5. Explicitly, r is thrifty if and only if it is an isomorphism over every stratum of Δ_X .

Proof of Lemma 3.16. In this situation there is an honest morphism $\operatorname{snc}(\Delta_Z) \to \Delta_X$, so the hypotheses of Lemma 3.9 are satisfied. We then apply Lemma 3.9 (ii).

Remark 3.17. In the case where the morphism $r: Z \to X$ of Lemma 3.16 is projective, [Har77, Thm. 7.17] implies that r is the blowup of some sheaf of ideals $\mathcal{I} \subseteq \mathcal{O}_X$ such that $V(\mathcal{I}) \subset X$ contains no stratum of Δ_X . If in addition $V(\mathcal{I})$ has simple normal crossings with Δ_X [Kol07, Def. 3.24], Lemma 3.16 can be obtained from known results on the effect of blowing up on dual complexes [Ste06, §2], [dFKX14, §9], [Wlo16, Prop. 2.1.6].

4. STRUCTURE SHEAVES OF STRATA AND THEIR DIRECT IMAGES

In this section we prove weak functoriality statements about the quasi-isomorphisms in Theorem 1.1, or alternatively those of [Kov19].

Lemma 4.1. Let S be scheme over a field k and let $f: X \to S$, $g: Y \to S$ are S-schemes that are smooth over k. Suppose $X \stackrel{r}{\leftarrow} Z \stackrel{s}{\to} Y$ is a proper birational equivalence over S such that both r and s are projective. Let C(Z) denote the category with objects the pairs $(E \subseteq X, F \subseteq Y)$ of smooth closed subschemes of X and Y such that

- (i) r and s are isomorphisms over the generic points of E and F respectively, and
- (ii) the birational map $s \circ r^{-1} \colon X \dashrightarrow Y$ sends the generic point of E to the generic point of F, and with morphisms $(E_1, F_1) \to (E_2, F_2)$ given by inclusions $E_1 \subseteq E_2$, $F_1 \subseteq F_2$. If $K \subset C(Z)$ is a finite subcategory, then there are proper birational equivalences $E \xleftarrow{r'} W \xrightarrow{s'} F$ compatible with Z in the sense that

$$E \xleftarrow{r'} W \xrightarrow{s'} F$$

$$\downarrow \circlearrowleft \qquad \downarrow_k \circlearrowleft \qquad \downarrow$$

$$X \xleftarrow{r} Z \xrightarrow{s} Y$$

$$(4.2)$$

commutes, and commutative diagrams

$$Rf_{*}\mathcal{O}_{X} \xrightarrow{\gamma_{X,Y}} Rf_{*}\mathcal{O}_{Y}$$

$$\downarrow \qquad \circlearrowleft \qquad \text{in } D^{+}(S).$$

$$Rf_{*}\mathcal{O}_{E} \xrightarrow{\gamma_{E,F}} Rf_{*}\mathcal{O}_{F}$$

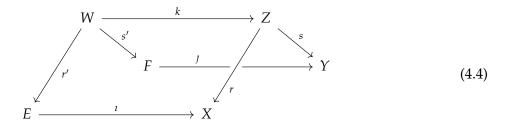

$$(4.3)$$

defining a natural transformation of functors $K^{op} \to D^+(S)$.

Proof. We proceed by descending induction over the poset K.

For each object $(E,F) \in \mathrm{Ob}(\mathcal{K})$, since X is smooth and r is an isomorphism over the generic point $\xi \in E$ we see that if $\tilde{E} \subseteq Z$ is the strict transform of E then $\tilde{E} \not\subset \mathrm{Sing}(Z)$, so in particular if non-CM $(Z) \subseteq Z$ is the non-Cohen-Macaulay locus then $\tilde{E} \not\subset \mathrm{non-CM}(Z)$ – similarly for F. By a theorem of Česnavičius, there exists $Macaulay fication \ \pi \colon \tilde{Z} \to Z$ such that π is an isomorphism over $Z \setminus \mathrm{non-CM}(Z)$ – explicitly, \tilde{Z} is Cohen-Macaulay and π is a projective birational morphism [Ces18, Thm. 1.6] (see also [Kaw00, Thm. 5.1]). It follows that $F \cap T$ and $F \cap T$ are projective and isomorphisms over the generic points of $F \cap T$ and $F \cap T$ and $F \cap T$ are projective and we may assume $F \cap T$ is Cohen-Macaulay.

Now suppose $(E, F) \in Ob(\mathcal{K})$ is *maximal* (categorically final), and let $W \subseteq Z \times_{X \times Y} E \times F$ be the component dominating E and F, and form the commutative diagram of S-schemes

Replacing W with a Macaulayfication $\pi' \colon \tilde{W} \to W$ if necessary, we may assume W is Cohen-Macaulay. Now by functoriality we have commutative diagrams

in D(X) and D(Y) respectively. The vertical arrows are isomorphisms since X, Y, E and F are all smooth, so in particular they have rational singularities, and W and Z are Cohen-Macaulay, so we

may apply [Kov19, Thm. 8.6]. Finally, pushing forward along f and g we obtain

$$Rf_{*}\mathcal{O}_{X} \xrightarrow{Rf_{*}i^{\sharp}} R(f \circ i)_{*}\mathcal{O}_{E}$$

$$Rf_{*}r^{\sharp} \downarrow \simeq \qquad \simeq \downarrow R(f \circ i)_{*}r'^{\sharp}$$

$$R(f \circ r)_{*}\mathcal{O}_{Z} \xrightarrow{R(f \circ r)_{*}k^{\sharp}} R(f \circ r \circ k)_{*}\mathcal{O}_{W} = R(f \circ i \circ r')_{*}\mathcal{O}_{W}$$

$$\parallel \qquad \qquad \parallel$$

$$R(g \circ s)_{*}\mathcal{O}_{Z} \xrightarrow{R(g \circ s)_{*}k^{\sharp}} R(g \circ s \circ k)_{*}\mathcal{O}_{W} = R(g \circ j \circ s')_{*}\mathcal{O}_{W}$$

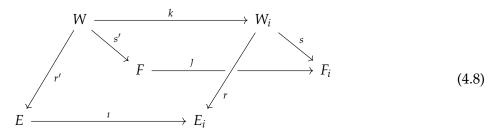

$$\cong \uparrow Rg_{*}s^{\sharp} \qquad \circlearrowleft \qquad R(g \circ j)_{*}s'^{\sharp} \uparrow \simeq$$

$$Rg_{*}\mathcal{O}_{Y} \xrightarrow{Rg_{*}j^{\sharp}} R(g \circ j)_{*}\mathcal{O}_{F}$$

$$(4.6)$$

For the inductive step, suppose $(E,F) \in \mathrm{Ob}(\mathcal{K})$ and let $\alpha_i \colon (E,F) \to (E_i,F_i)$, $i=1,\ldots,r$ be the morphisms in \mathcal{K} with source (E,F). By inductive hypothesis, for each i we have a Cohen-Macaulay S-scheme W_i and a projective birational equivalence $E_i \stackrel{r_i}{\leftarrow} W_i \stackrel{s_i}{\rightarrow} F_i$ inducing a morphism $\gamma_{E_i,F_i} \colon Rf_*\mathcal{O}_{E_i} \to Rg_*\mathcal{O}_{F_i}$ – using the above construction, we can ensure that for any \mathcal{K} -morphism $(E',F') \to (E_i,F_i)$ the map r_i is an isomorphism over E', and similarly for F_i . Consider the cartesian diagram

and let $W \subseteq (E \times_S F) \times_{\prod_{S,i=1}^r (E_i \times F_i)} \prod_{S,i=1}^r W_i$ be the component dominating E and F. Note that r',s' are projective since $\prod_{S,i} (r_i \times_S s_i)$ is projective by hypothesis. As above, we may replace W by a projective Macaulayfication while retaining the property that r',s' are isomorphisms over the generic points of $E' \subset E$, $F' \subset F$ for every K-morphism $(E',F') \to (E,F)$. Now by design for each i there is a commutative diagram

and arguing as in the base case we obtain from (4.8) a commutative diagram in $D^+(S)$ of the form

$$Rf_{*}\mathcal{O}_{E_{i}} \xrightarrow{\gamma_{E_{i}}, F_{i}} Rf_{*}\mathcal{O}_{F_{i}}$$

$$\downarrow \qquad \circlearrowleft \qquad \downarrow \qquad \qquad (4.9)$$

$$Rf_{*}\mathcal{O}_{E} \xrightarrow{\simeq} Rf_{*}\mathcal{O}_{F}$$

Corollary 4.10. Let S be a scheme over a field k and let (X, Δ_X) and (Y, Δ_Y) be simple normal crossing pairs over k with morphisms $f: X \to S$ and $g: Y \to S$. Suppose $X \xleftarrow{r} Z \xrightarrow{s} Y$ is a thrifty proper birational

equivalence over S such that both r and s are projective. Let \mathcal{D} be the common dual complex of Δ_X and Δ_Y (see Remark 3.13) and for a simplex $\sigma \subseteq \mathcal{D}$ let $D_X(\sigma) \subseteq X$, $D_Y(\sigma) \subseteq Y$ be the corresponding strata. In this situation there is a natural transformation of functors $Face(\mathcal{D}) \to D^+(S)$ from $Rf_*\mathcal{O}_{D_X(\sigma)}$ to $Rg_*\mathcal{O}_{D_Y(\sigma)}$, compatible with restrictions from $Rf_*\mathcal{O}_X$ and $Rg_*\mathcal{O}_Y$, and hence a commutative diagram in $D^+(S)$ of the form

$$Rf_{*}\mathcal{O}_{X} \to \prod_{\sigma \in \mathcal{D}^{0}} Rf_{*}\mathcal{O}_{D_{X}(\sigma)} \to \prod_{\sigma \in \mathcal{D}^{1}} Rf_{*}\mathcal{O}_{D_{X}(\sigma)} \to \prod_{\sigma \in \mathcal{D}^{2}} Rf_{*}\mathcal{O}_{D_{X}(\sigma)} \to \cdots$$

$$\downarrow \qquad \qquad \downarrow \gamma^{0} \qquad \qquad \downarrow \gamma^{1} \qquad \qquad \downarrow \gamma^{2}$$

$$Rg_{*}\mathcal{O}_{Y} \to \prod_{\sigma \in \mathcal{D}^{0}} Rg_{*}\mathcal{O}_{D_{Y}(\sigma)} \to \prod_{\sigma \in \mathcal{D}^{1}} Rg_{*}\mathcal{O}_{D_{Y}(\sigma)} \to \prod_{\sigma \in \mathcal{D}^{2}} Rg_{*}\mathcal{O}_{D_{Y}(\sigma)} \to \cdots$$

$$(4.11)$$

Proof. We apply Lemma 4.1 to the finite subcategory $\mathcal{K} \subset \mathcal{C}(Z)$ with objects $(D_X(\sigma), D_Y(\sigma))$ for $\sigma \subseteq \mathcal{D}$. Evidently, this \mathcal{K} is equivalent to Face (\mathcal{D}) .

5. A MORPHISM OF RESTRICTION TRIANGLES

The main result of this section is

Lemma 5.1. Let S be a base scheme over a field k and let and let (X, Δ_X) and (Y, Δ_Y) be simple normal crossing schemes over k with morphisms $f: X \to S$, $f: Y \to S$. If $X \xleftarrow{r} Z \xrightarrow{s} Y$ is a thrifty proper birational equivalence over S then there is an isomorphism of distinguished triangles

$$Rf_{*}\mathcal{O}_{X}(-\Delta_{X}) \longrightarrow Rf_{*}\mathcal{O}_{X} \longrightarrow Rf_{*}\mathcal{O}_{\Delta_{X}} \xrightarrow{+1} \cdots$$

$$\downarrow^{\gamma'} \qquad \qquad \downarrow^{\gamma'} \qquad \qquad in \ D^{+}(S).$$

$$Rg_{*}\mathcal{O}_{Y}(-\Delta_{Y}) \longrightarrow Rg_{*}\mathcal{O}_{Y} \longrightarrow Rg_{*}\mathcal{O}_{\Delta_{Y}} \xrightarrow{+1} \cdots$$

$$(5.2)$$

For the most part, this consists of combining Corollaries 2.7 and 4.10 to obtain the isomorphisms γ and γ'' – after that, the existence of γ' is guaranteed since $D^+(S)$ is triangulated, and the fact that γ' is an isomorphism follows from the 5-lemma.
